

FontGen

Generating fonts using a neural net

Matt Gaikema

```
In[1]:= ClearAll["Global`*"]
SetDirectory[NotebookDirectory[]];
```

I spend a lot of time trying to identify and download fonts, so a program that could do it for me would be wonderful. There are many academic papers on the subject, but none of them have published their code, so I decided to implement it myself and learn more about deep learning along the way.

Data

The data is a whopping 13+ gigabytes and was scraped from the internet by someone else. It can be downloaded [here](#).

```
Import["fonts.hdf5", {"Dimensions"}]
```

```
<| /fonts → {56443, 62, 64, 64} |>
```

I debugged the neural net using a much smaller dataset, consisting of my personal collection of fonts. The smaller dataset was created by running a script written by the same guy who got the original data.

```
Import["fonts.small.hdf5", {"Dimensions"}]
f = Import["fonts.small.hdf5", {"Datasets", "fonts"}];
(* Show an example character. *)
Image[f[[1]][[1]]]
```

```
<| /fonts → {21, 62, 64, 64} |>
```

Network

Each letter is 64x64 pixels.

```
(* We use 4 letters as input... *)
4 * 64^2
(* ... and get 62 letters as output. *)
62 * 64^2
```

```
16 384
```

```
253 952
```

There are $4 * 64^2 = 16,384$ input neurons, and $62 * 64^2 = 253,952$ output neurons. The letters chosen for the inputs are “B”, “A”, “S”, and “Q”.

```
(* http://bit.ly/2oeHyZX *)
Range[0, 25];
letters = AssociationThread[ToUpperCase[#] & /@ Alphabet[], %];
Lookup[letters, {"B", "A", "S", "Q"}]
Image[f[[1]][[#+1]]] & /@ %
```

```
{1, 0, 18, 16}
```

Architecture

Here is the architecture that I used for the model. Many of the parameters were determined through tedious trial-and-error.

In[36]:=

```
(* Created using Keras's `plot_model` function: https://
keras.io/visualization/ *)
Import["img/model.png"]
```

Out[36]=

After training is complete, running `model.save_weights()` saves the model and its weights to an HDF5 file, which can be loaded to recreate the model (see the documentation).

In[35]:=

```
Import["model.hdf5", {"Dimensions"}]
```

Out[35]=

```
<| /batch_normalization_1/batch_normalization_1/beta:0 → {253 952},
/batch_normalization_1/batch_normalization_1/gamma:0 → {253 952},
/batch_normalization_1/batch_normalization_1/moving_mean:0 → {253 952},
/batch_normalization_1/batch_normalization_1/moving_variance:0 → {253 952},
/conv2d_1/conv2d_1/bias:0 → {8}, /conv2d_1/conv2d_1/kernel:0 → {4, 4, 1, 8},
/conv2d_2/conv2d_2/bias:0 → {8}, /conv2d_2/conv2d_2/kernel:0 → {4, 4, 1, 8},
/conv2d_3/conv2d_3/bias:0 → {8}, /conv2d_3/conv2d_3/kernel:0 → {4, 4, 1, 8},
/conv2d_4/conv2d_4/bias:0 → {8}, /conv2d_4/conv2d_4/kernel:0 → {4, 4, 1, 8},
/conv2d_5/conv2d_5/bias:0 → {10}, /conv2d_5/conv2d_5/kernel:0 → {4, 4, 32, 10},
/dense_1/dense_1/bias:0 → {253 952}, /dense_1/dense_1/kernel:0 → {10, 253 952} |>
```

Evaluation

```
(* A function which transforms a list of image arrays to a list of images. *)
displayFont[f_] := Map[Map[Image, #] &, f];
```

I tested the model on the font Ubuntu Mono, which is available for download [here](#).

In[37]:=

```
Import["test.hdf5", {"Dimensions"}]
testInput = Import["test.hdf5", {"input"}];
displayFont[testInput]
output = Import["test.hdf5", {"output"}];
displayFont[output]
```

Out[37]=

```
<| /input → {4, 1, 64, 64, 1}, /output → {1, 62, 64, 64} |>
```

Out[39]=

```
{ { B }, { A }, { S }, { Q } }
```

Out[41]=

References

```
In[23]:= (* There is no better way to insert references on Mac/Linux. See http://bit.ly/2lo3Pkc *)
Import["sources.bib"]
